Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

EP 0 791 340 B1

Description

[0001] The invention relates to a temporary filter catheter such as used for instance during thrombolytic treatment. In that case the filter is arranged inside the vena cava and prevents blood thrombi from circulating freely through the vascular system and finishing up in places which could endanger the health of the patient.

[0002] For a certain group of patients, for whom such interventions entail a high degree of risk, it may be necessary to keep such a catheter for a longer period of time, for instance for a period of more than 10 days, in place.

[0003] Commonly used filter catheters of this type, see for example the disclosure of FR-A-2 652 267, comprise, arranged at a distal end of a tube-like basic body, a filter element which is made up of a number of strips arranged spaced out around the circumference and connected to the basic body, which strips can be bent outwards by moving the opposite ends towards each other in order to be brought into the operative state by doing so. Another slightly different but pertinent example of filter catheters is Known from FR-A-2 696 092. The maximum period such filter catheters can stay inside the body is limited by the fact that the tissue of the wall of the blood vessel concerned, against which the strip-shaped elements are positioned, encapsulate these strips, so that the filter element grows into the tissue. Consequently such a filter can only be removed by damaging the tissue, which is obviously undesirable.

[0004] The object of the invention is to provide a filter catheter of the type referred to, which can stay for a long period of time inside the body of the patient.

[0005] With the filter catheter according to the invention this is achieved because the relatively distal ends of the strips which define the filter element are connected with the basic body by connecting means in a detachable manner. On removing the catheter, the distal ends of the strips are disconnected after which the filter element can be withdrawn without damaging the tissue. On withdrawal, the strips slide through the 'channels' which have been formed in the tissue surrounding the strips.

[0006] A suitable embodiment of the filter catheter according to the invention is characterised in claim 2.

[0007] Disconnecting the distal ends of the strips can be done by displacing the inner tube-like body in relation to the outer tube-like body in a distal direction. By doing so a tensile force is applied to the strips, which consequently are detached from the connecting means.

[0008] A suitable embodiment is additionally characterised in claim 3. As long as a certain minimum tensile force is not applied to the strips, the sleeve retains the distal ends of the strips. As soon as this minimum tensile force is exceeded, the ends of the strips will slide from under the sleeve so that they are detached from the connecting means.

[0009] Preferably the measure as set out in claim 4 is

additionally employed. The ends of the strips are secured elastically, so that a reliable connection is maintained until the moment the connection has to be broken. Because of the elasticity of the sleeve, the disconnecting force can be administered accurately.

[0010] In order to achieve a positive retaining of the distal ends of the strips, the measure as set out in claim 5 is preferably employed. A suitable embodiment is additionally characterised in claim 6.

[0011] The invention will be explained in greater detail in the following description with reference to the attached drawings.

Figure 1 shows the distal end of an example of an embodiment of a catheter according to the invention during the introduction thereof.

Figure 2 shows a detailed view cut through at the arrow II of figure 1.

Figure 3 illustrates the end of the catheter shown in figure 1 with the filter element unfolded.

Figure 4 shows a view corresponding to figure 3 after a relatively long stay inside the body of the patient, and where the strips are grown into the tissue.

Figure 5 illustrates the removal of the filter after disconnecting the ends of the strips.

Figure 6 shows a view corresponding to figure 2 with the ends of the strips of the filter element detached.

Figure 7 illustrates an alternative embodiment of connecting means for a catheter according to the invention.

[0012] In figure 1 the distal end-section of a catheter 1 according to a preferred embodiment of the invention is shown. The catheter 1 has been introduced into a blood vessel 2 of a patient and the filter element 6 of this catheter still has to be unfolded in order to be able to carry out the filter function.

[0013] The catheter 1 comprises an outer tube-like body 3 inside of which an inner tube-like body 4 has been received in a movable manner. The inner tube-like body has a lumen through which a guide wire 5 extends when positioning the catheter and in particular the filter element 6 thereof.

[0014] In the case of the example of this preferred embodiment the filter element 6 is formed by a number of strips, which are made up of sections of the wall of the outer tube-like body 3, which are separated from one another by longitudinal cuts.

[0015] The relatively proximal ends of the strips 7, that is to say the ends of these strips on the right-hand side as seen in figure 1, form a whole with the outer tube-like body 3.

[0016] The relatively distal ends 10 of the strips 7 are connected to the inner tube-like element in a detachable manner by connecting means 8. The connecting means 8 retain the distal ends 10 of the strips 7 by means of a

clamping connection. This clamping connection is obtained because the connecting means 8 comprise a sleeve 11 made of an elastic material, for instance silicone rubber.

[0017] The sleeve 11 has been fixed to the catheter by means of a layer of cured plastic material 13, for instance a cured epoxy. The end-section 14 of the catheter 1 has preferably been made of a soft material in order to achieve a maximum atraumatic action when introducing the catheter.

[0018] As can be seen in figure 2, a marking ring 12 has been arranged around the inner tube-like body 4 and a second marking ring has been arranged around the outer tube-like body 3. Both rings have for instance been made of gold to make the position of the filter element clearly visible on an X-ray screen in a catheterisation laboratory.

[0019] Figure 3 shows the unfolded, operative state of the filter element 6. This state is brought about when the catheter 1, and in particular the filter element 6, has been manoeuvred in the target position inside the blood vessel 2. The guide wire 5 can then be removed.

[0020] In order to unfold the filter element 6, the inner tube-like body 4 is moved in relation to the outer tube-like body 3 in a proximal direction. As a result the ends of the strips 7 are moved towards each other, so that these strips bend outwards until they make contact with the wall of the blood vessel 2. The connecting means 8 retain the ends of the strips 7 in a reliable manner.

[0021] When the catheter is left inside the body with the filter element unfolded in this manner for a longer period of time, tissue 20 will start growing around strips 7 positioned against the wall of the blood vessel 2. The strips 7 form 'passages' as it were inside this tissue 20. The state in which the strips 7 have grown together with the tissue has been illustrated in figure 4. When in this situation the catheter would be removed just like that, the tissue grown around the strips 7 would have to be torn, with all the attendant risks.

[0022] With the catheter described here, the distal ends 10 of the strips 7 are detached from the connecting means 8 however before the catheter is removed.

[0023] Detaching the said distal ends is simply done by moving the inner tube-like element 4 in relation to the outer tube-like element 3 in a distal direction. The elastic sleeve 11 is then slid off the distal ends 10 of the strips 7, as a result of which these ends 10 are released in the manner illustrated in the figures 5 and 6.

[0024] When the catheter is subsequently removed, the strips 7 will slide easily through the passages 21 formed inside the tissue 20, without any damage being done to this tissue 20. In other words, the catheter can be removed without problems and without trauma.

[0025] As can be seen in the figures 2, 5 and 6, the ends 10 of the strips 7 are provided with a projection which ensures a good grip of the sleeve on the ends 10.

[0026] Figure 7 shows a somewhat different embodiment of the strips 7, in which case the projections, indi-

cated here with the reference number 25, are formed by a depression 24 in the outside surface of each strip 7 at a small distance from the distal end thereof. The depth of the depression 24 is equal to the thickness of the sleeve 11, so that the outside surface of the catheter with the strips 7 is even and smooth in the connected state.

[0027] The invention is not limited to the embodiment shown and described herein. Specifically the connecting means with which the relatively distal ends of the strips are connected with the basic body can be embodied in other ways than shown. The distal ends of the strips can be connected by adhesives, pre-cut areas, hooks, and so on and so forth. Also the end-section 14 can be embodied such that it is directly connected to the elastic sleeve 11, so that end-section 14 and ring 4 and element 13 form one element.

20 Claims

1. Filter catheter (1) comprising a tube-like basic body with a proximal and a distal end, a filter element (6) arranged at the distal end which has been formed by a number of strips (7) arranged spaced out around the circumference which are connected to the basic body with both ends, **characterized in that** the relatively distal ends (10) of the strips are connected with the basic body in a detachable manner by connecting means (8).
2. Filter catheter as claimed in claim 1, wherein the basic body comprises an outer tube-like body (3) and an inner tube-like body (4) received inside it in a movable manner, the strips have been connected with their relatively proximal ends to the outer tube-like body and with their relatively distal ends to the inner tube-like body and wherein the connecting means (8) retain the distal ends (10) of the strips (7) by means of a clamping connection.
3. Filter catheter as claimed in claim 2, wherein the connecting means comprise a sleeve connected to the inner tube-like body and clasped around the distal ends of the strips.
4. Filter catheter as claimed in claim 3, wherein the sleeve has been made of an elastic material such as silicone rubber.
5. Filter catheter as claimed in one of the previous claims, wherein the distal ends of the strips comprise a projection.
6. Filter catheter as claimed in claim 5, wherein the projection is formed by a remaining wall section adjoining a depression in an outside surface of each strip at a small distance from the distal end thereof.

Patentansprüche

1. Filterkatheter (1) mit einem schlauchartigen Grundkörper mit einem proximalen und einem distalen Ende, einem Filterelement (6) angeordnet an dem distalen Ende, das durch eine Anzahl von Streifen (7) gebildet ist, die um den Umfang herum verteilt angeordnet sind und mit dem Grundkörper mit beiden Enden verbunden sind, **dadurch gekennzeichnet, dass** die relativ distalen Enden (10) der Streifen mit dem Grundkörper durch Verbindungsmittel (8) lösbar verbunden sind. 5
2. Filterkatheter nach Anspruch 1, bei dem der Grundkörper einen äußeren schlauchartigen Körper (3) und einen darin bewegbar aufgenommenen inneren schlauchartigen Körper (4) aufweist, wobei die Streifen mit ihren relativ proximalen Enden mit dem äußeren schlauchartigen Körper und mit ihren relativ distalen Enden mit dem inneren schlauchartigen Körper verbunden sind, und die Verbindungsmittel (8) die distalen Enden (10) der Streifen (7) mittels einer Einklemmverbindung festhalten. 10
3. Filterkatheter nach Anspruch 2, bei dem die Verbindungsmittel eine Hülse aufweisen, die mit dem inneren schlauchartigen Körper verbunden ist und um die distalen Enden der Streifen umgreift. 15
4. Filterkatheter nach Anspruch 3, bei dem die Hülse aus einem elastischen Material wie Silicon Gummi besteht. 20
5. Filterkatheter nach einem der vorhergehenden Ansprüche, bei dem die distalen Enden der Streifen einen Vorsprung aufweisen. 25
6. Filterkatheter nach Anspruch 5, bei dem der Vorsprung durch einen verbleibenden Wandabschnitt gebildet wird, der an eine Vertiefung in einer Außenfläche jedes Streifens in einem kleinen Abstand von dem distalen Ende derselben angrenzt. 30
2. Cathéter à filtre selon la revendication 1, selon lequel le corps de base comprend un corps (3) de type tube extérieur et un corps (4) de type tube intérieur logé à l'intérieur de ce dernier de manière mobile, les bandes sont raccordées par leurs extrémités relativement proximales au corps de type tube extérieur et par leurs extrémités relativement distales au corps de type tube intérieur, selon lequel les moyens de raccordement (8) retiennent les extrémités distales (10) des bandes (7) au moyen d'un élément de serrage. 35
3. Cathéter à filtre selon la revendication 2, selon lequel les moyens de raccordement comprennent un manchon relié au corps de type tube intérieur et serré autour des extrémités distales des bandes. 40
4. Cathéter à filtre selon la revendication 3, selon lequel le manchon est réalisé en un matériau élastique comme du caoutchouc de silicone. 45
5. Cathéter à filtre selon l'une quelconque des revendications précédentes, selon lequel les extrémités distales des bandes comprennent une projection. 50
6. Cathéter à filtre selon la revendication 5, selon lequel la projection est formée par une section de paroi restante adjacente à une dépression formée dans une surface extérieure de chaque bande à une faible distance de l'extrémité distale de cette dernière. 55

Revendications

1. Cathéter à filtre (1) comprenant un corps de base de type tube avec une extrémité proximale et une extrémité distale, un élément formant filtre (6) placé à une extrémité distale qui se compose d'un certain nombre de bandes (7) placées de manière à être espacées autour de la circonférence, qui sont raccordées au corps de base par leurs deux extrémités, **caractérisé en ce que** les extrémités relativement distales (10) des bandes sont raccordées au corps de base d'une manière amovible par des moyens de raccordement (8). 45
